

Building a Service Layer in a Vendor Agnostic Way

A practical approach to bridging the gap between business services and network implementation

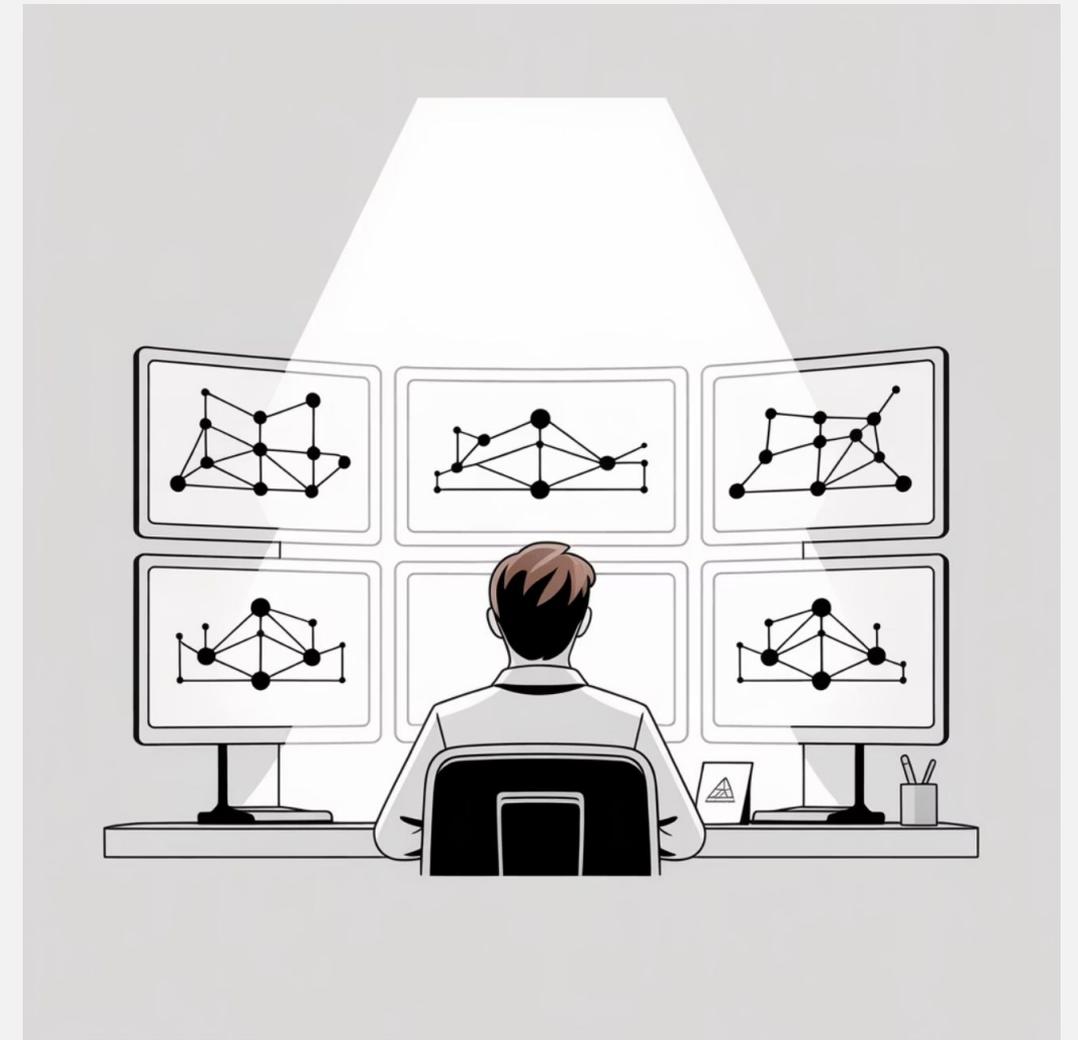

About me - Baptiste Girard

ISP Experience

With years of experience in the ISP domain, I deeply understand operational pain points and the challenges of network automation.

OpsMill & Infracub

Currently working at OpsMill, the company behind Infracub, developing solutions for network automation challenges

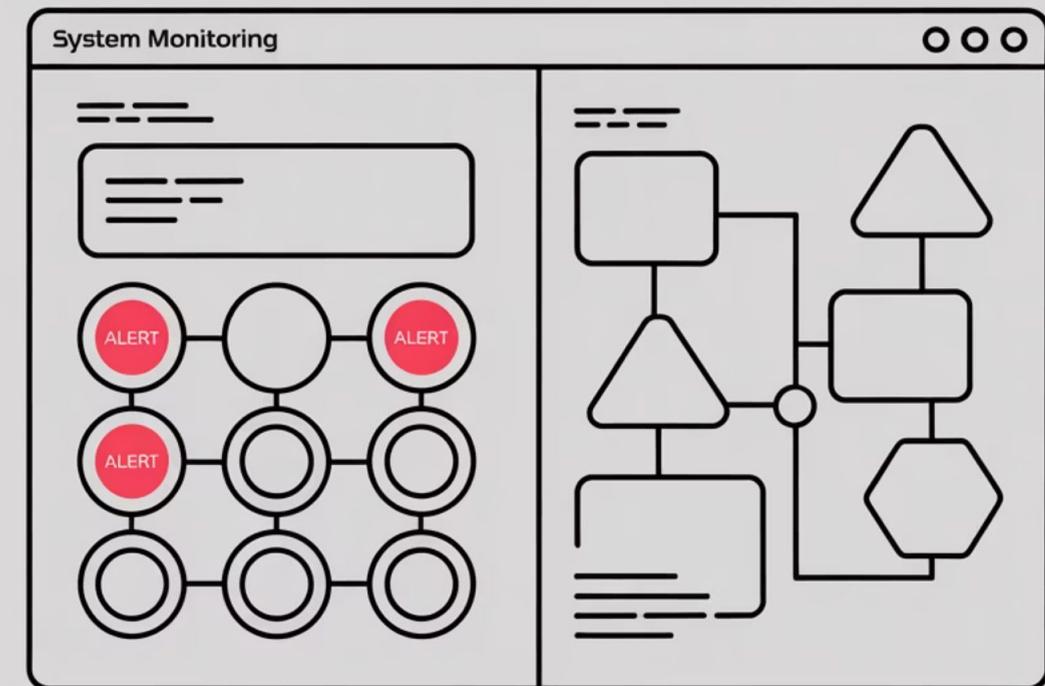

The Monitoring Paradox

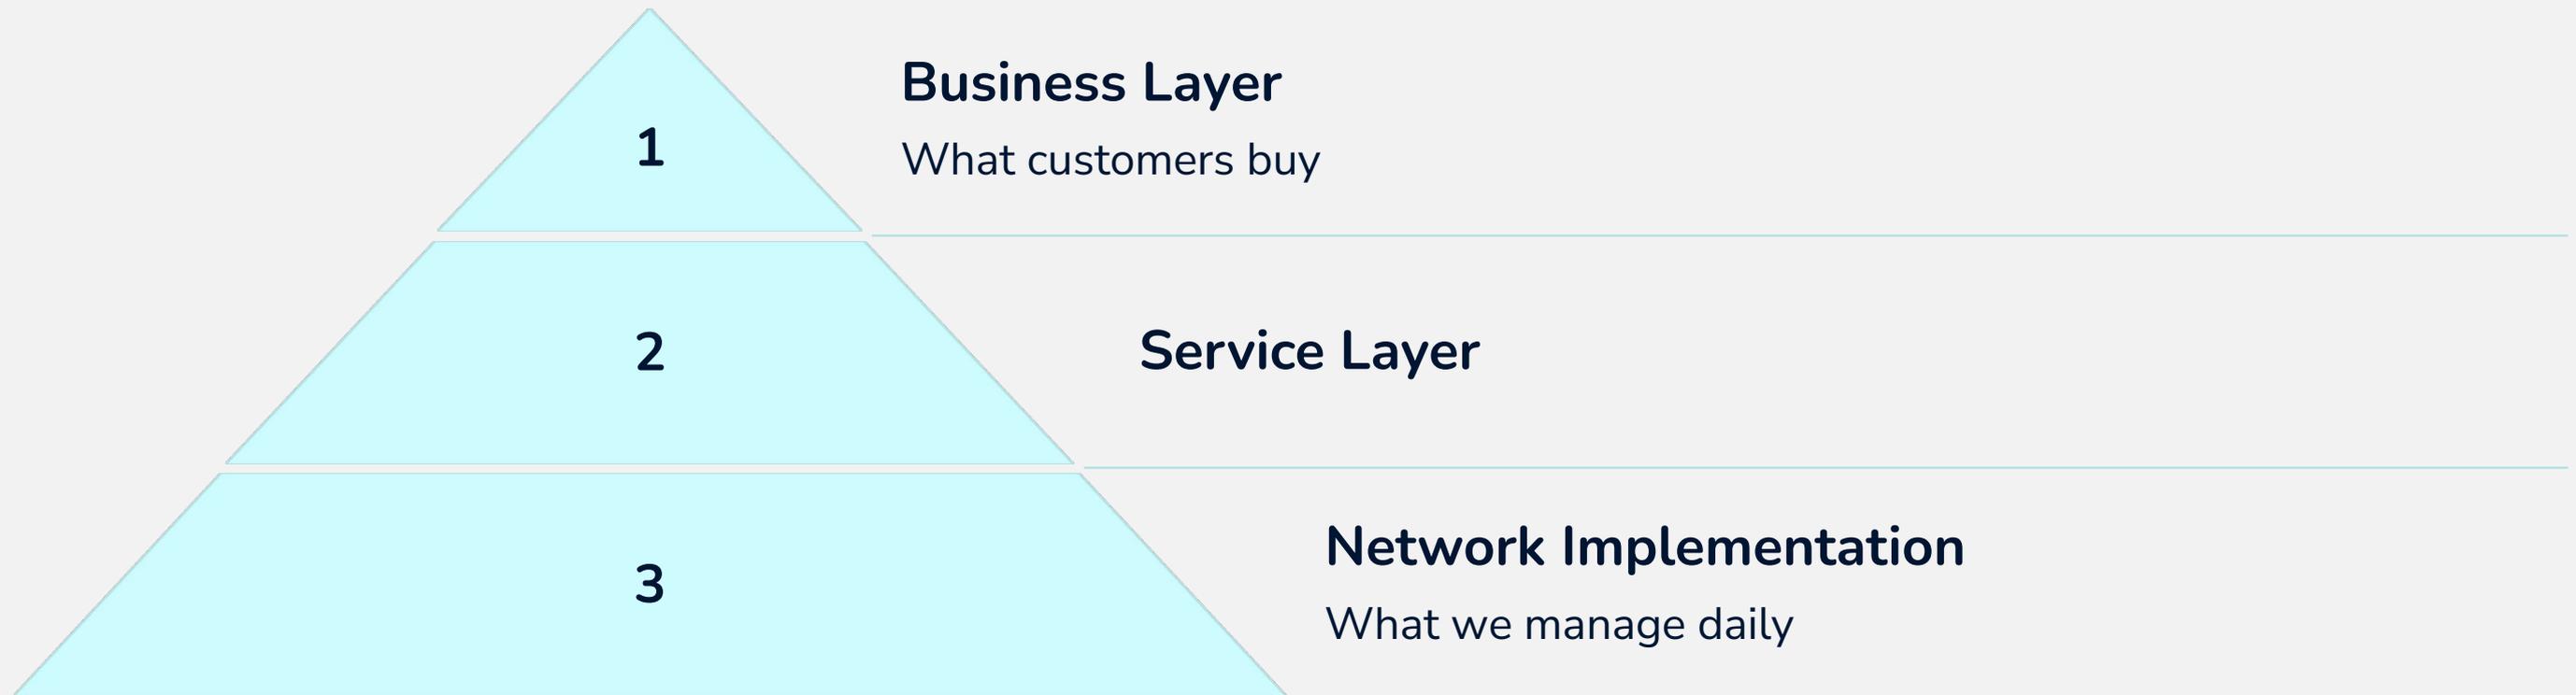

| "I don't need a source of truth. I already have my monitoring."

But monitoring only tells you an interface is **down**... It doesn't tell you if that interface **SHOULD** be down, or what services depend on it.

Monitoring gives you the "**is**", you need the "**should**" to understand business impact.

The Service Layer challenge

Customers buy "10Gbps dedicated internet" or "MPLS VPN" – but we manage VLANs, interfaces, routing protocols, and ACLs

Key benefits: Service lifecycle automation, proactive capacity planning, automated billing ...

Current Options

Rigid CMDBs

Force your unique services into predefined boxes that don't match reality

Homemade Solutions

Expensive to build, harder to maintain

Multiple Systems

ServiceNow + IPAM + Excel + Visio = Data silos and synchronization nightmares

Result: Lot of time fighting tools, hard to reach the full potential

Infracore

Flexible Platform

Adapts to your organization's unique needs and processes rather than forcing you to change

Version Control & Branching

Apply software development practices to infrastructure management

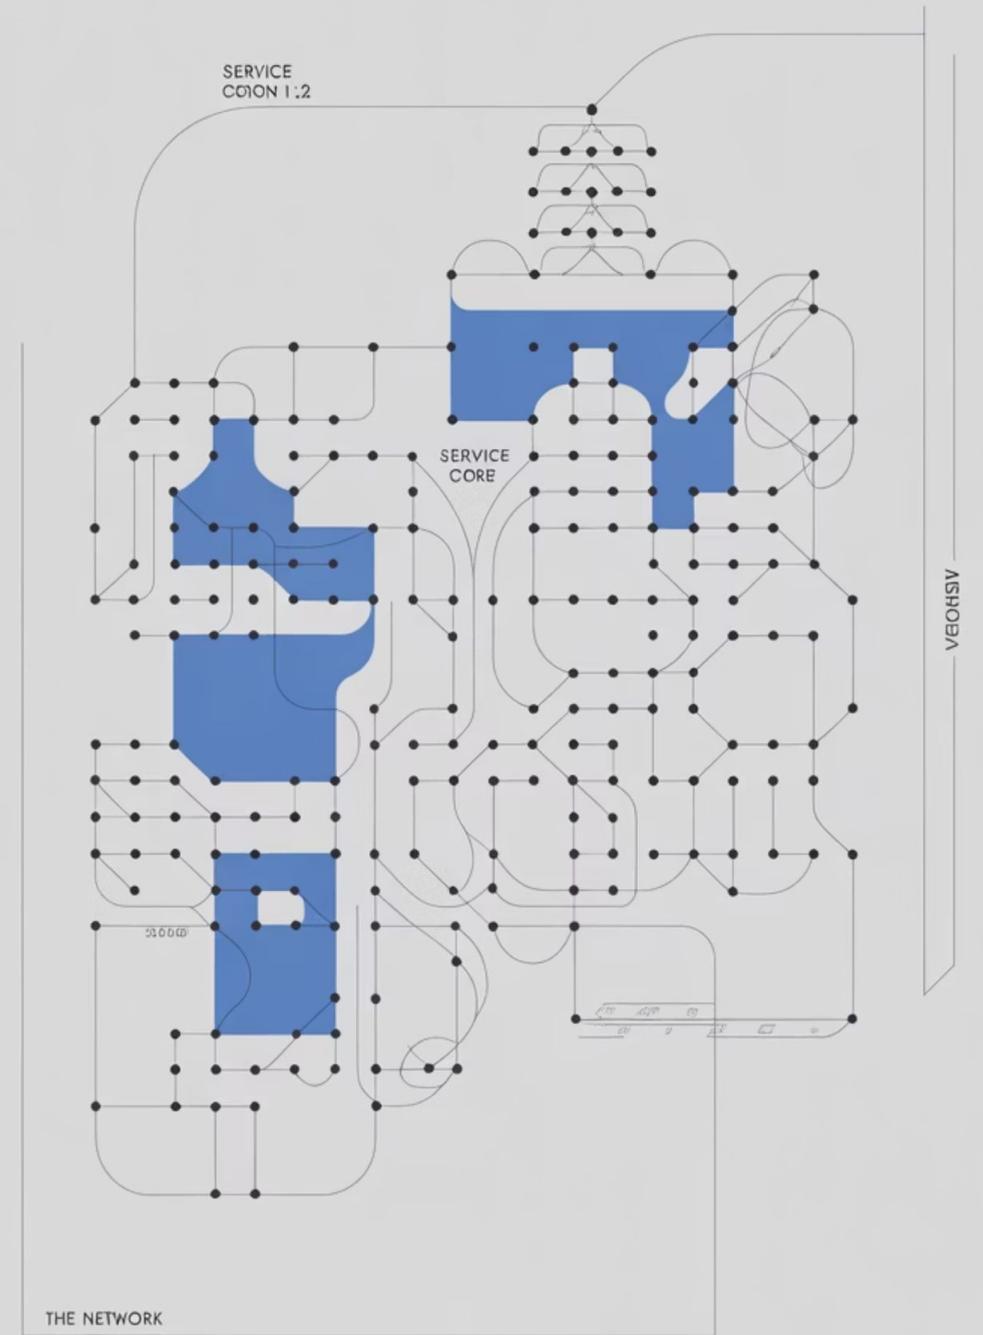

Unified Storage

Single platform for data, configurations, templates, and automation scripts

Step 1

Define Your Service Schema

Model your services exactly as your business needs them – no compromises

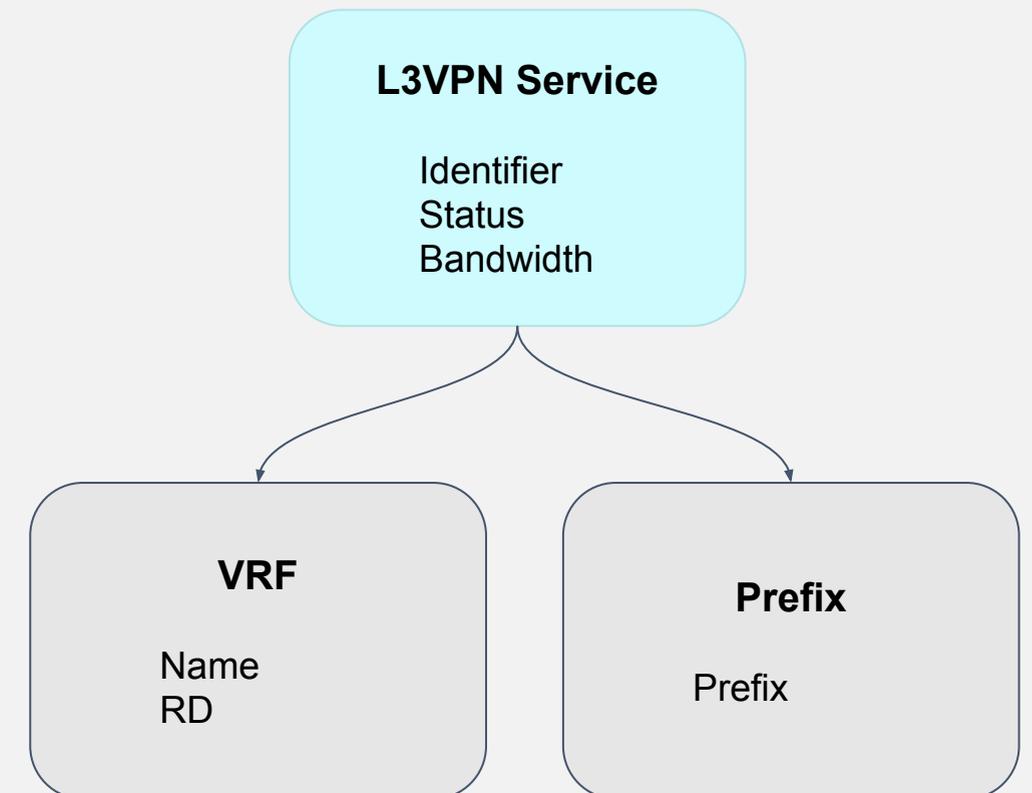

Schema Definition

A schema defines the **structure, format, and constraints** of data, specifying **how data is organized** and interpreted in databases or data models.

It is important because it **ensures data consistency, integrity, and facilitates communication between different systems** by providing a shared understanding of the data's structure.

Build a robust data model that can be leveraged across your entire pipeline

Example: L3VPN Service Definition

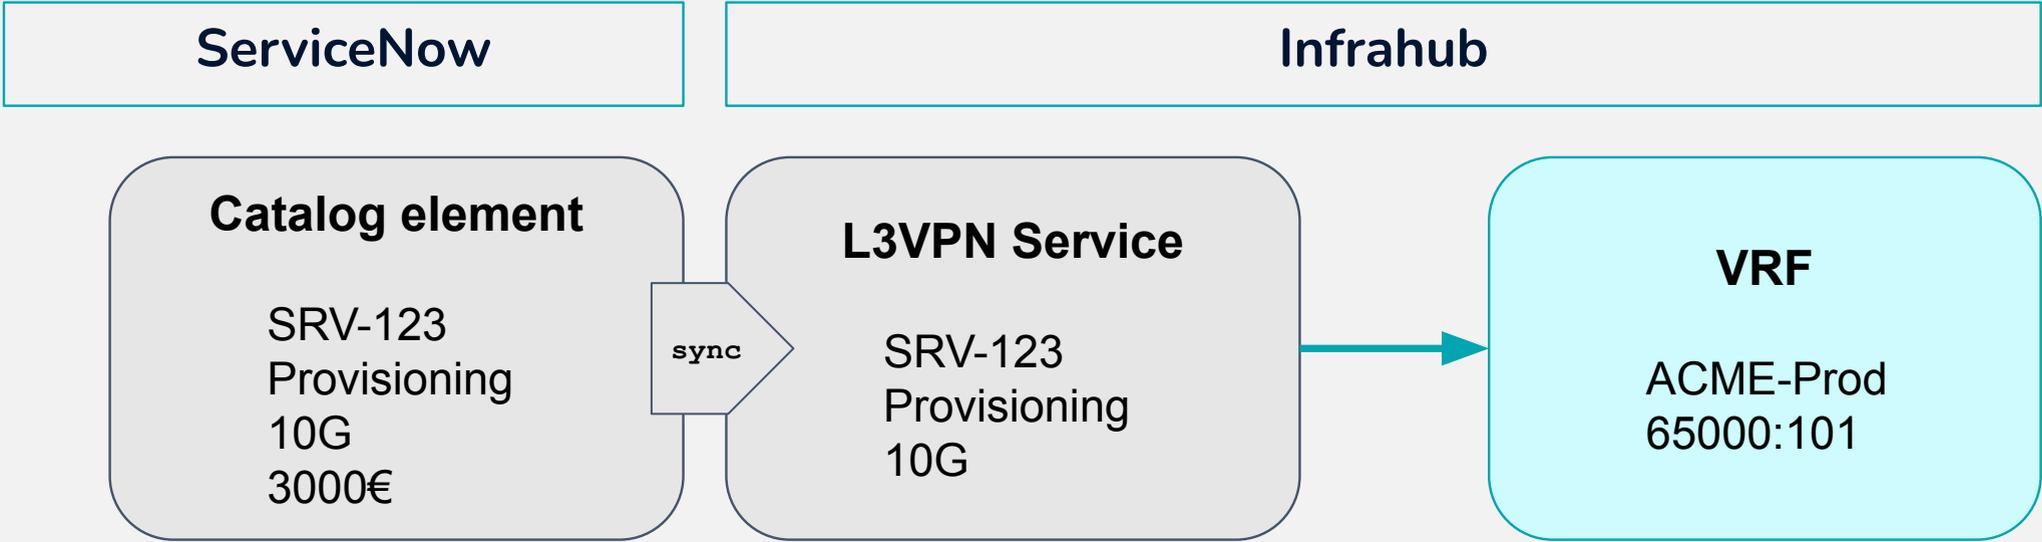

No Assumptions, Full Control

With flexible schemas, **Infrahub** lets you define custom types that match how you design and implement services. No more forcing your services into predefined templates.

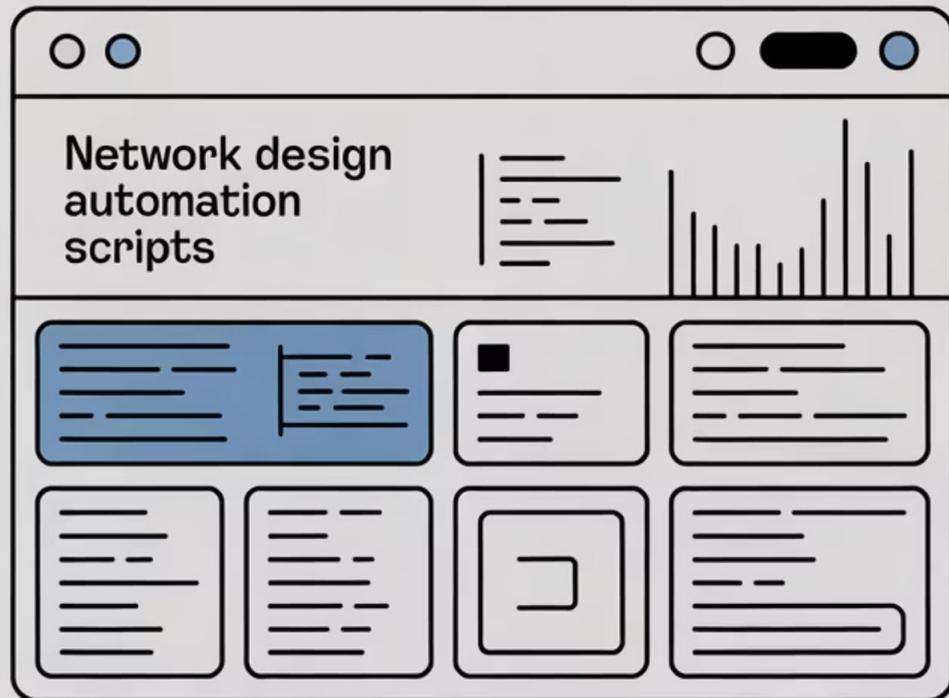

```
! example.yml
1  nodes:
2    - name: L3VPN
3      namespace: Service
4      icon: mdi:ethernet
5      attributes:
6        - name: identifier
7          kind: Text
8          unique: true
9          optional: false
10       - name: status
11         kind: Dropdown
12         optional: false
13         default_value: draft
14         choices:
15           - name: draft
16           - name: in-delivery
17           - name: active
18           - name: in-decomissioning
19           - name: decomissioned
20       relationships:
21         - name: vrf
22           peer: NetworkVRF
23           cardinality: one
24           optional: true
```

Integrate various data sources

Customer data synced from ServiceNow automatically populates the service model

Create strong integration and a comprehensive overview of your network implementation.

Step 2

Codify Your Network Design

Transform tribal knowledge into structured, repeatable code

From Tribal Knowledge to Code

“Network design lives in Visio diagrams and senior engineers' heads”

Infrahub Generators are python scripts that **encode your design patterns** and automatically **translate service requests into implementation.**

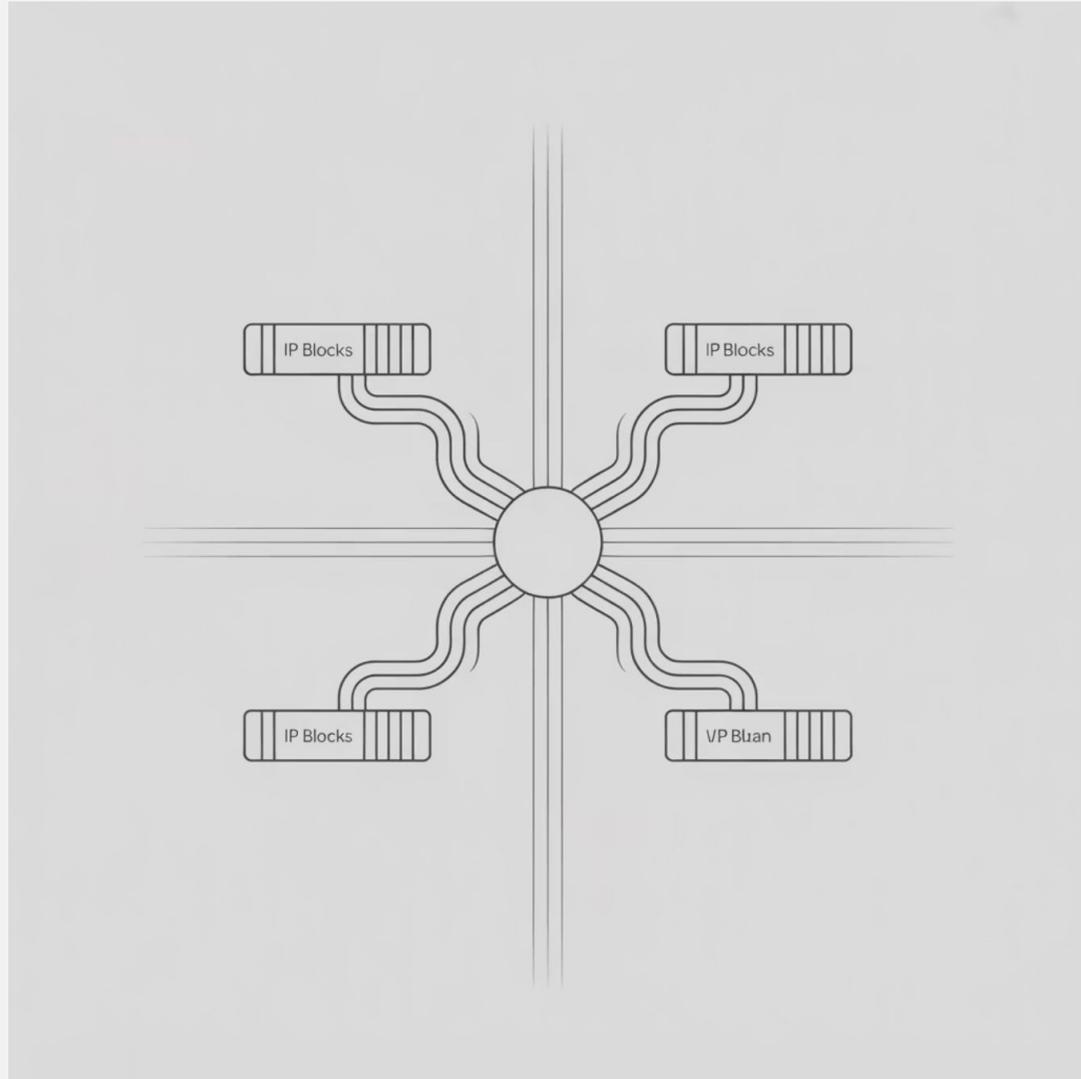

VRF should be named after service identifier

IP address should be allocated from the designated customer prefix

Gateway IP address is the first available IP of the prefix

Intelligent Resource Management

Define Resource Pools

IP prefixes, VLAN ranges, AS numbers, and other network resources

Automatic Allocation

Works with generators, no more spreadsheet tracking or manual assignment

Guaranteed Uniqueness

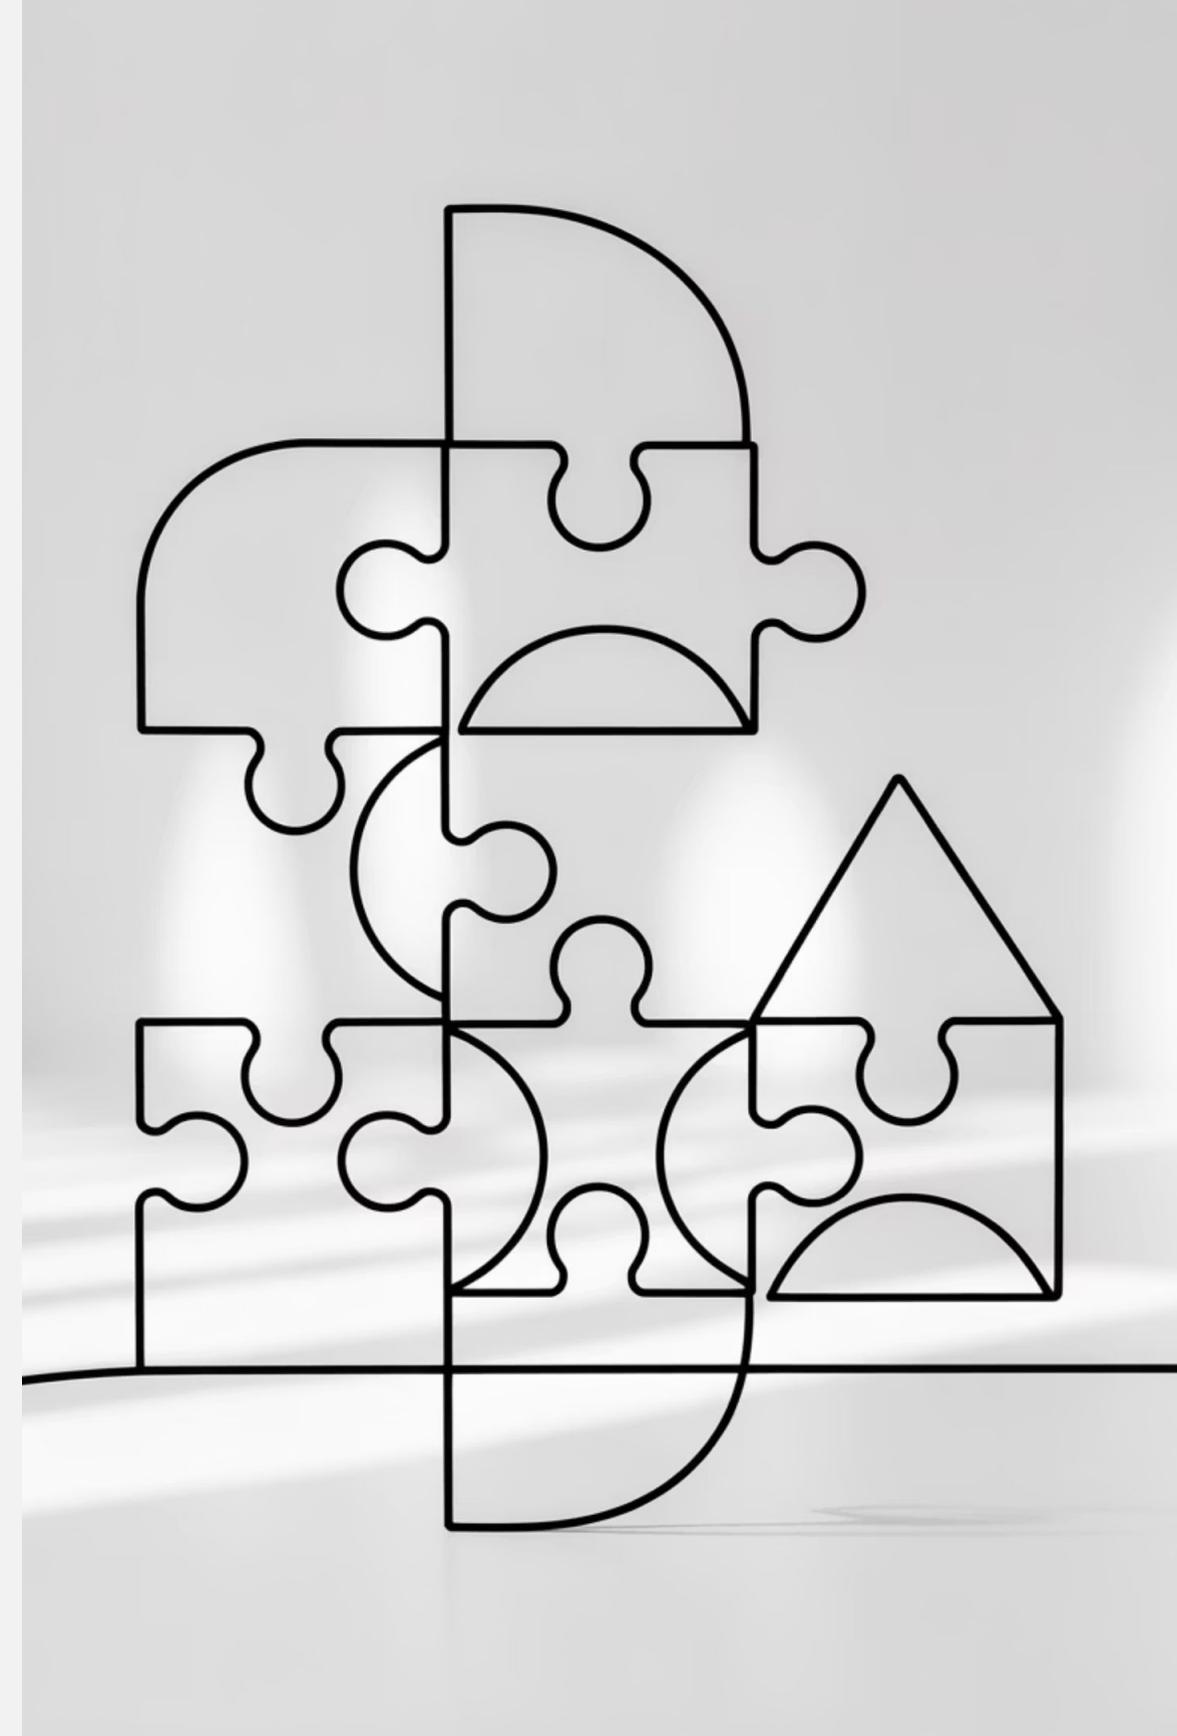

Prevent conflicts before they happen with built-in validation

Result: Ship consistent, predictable services with engineering confidence

Step 3

Implement Services

Transform your service model into vendor-specific implementations

From Data Model to Device Reality

Transforms let you **define vendor-specific logic** that converts a generic service into a deployable configuration for the field.

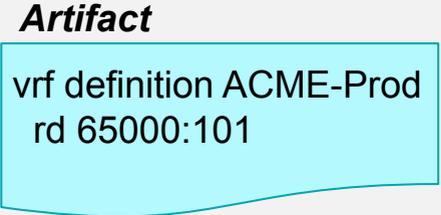

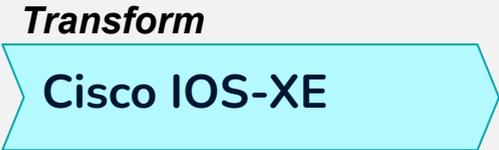

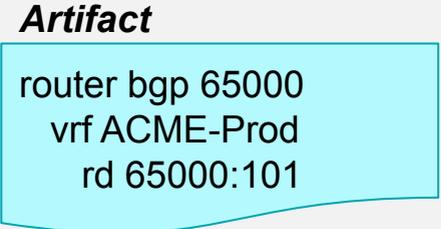

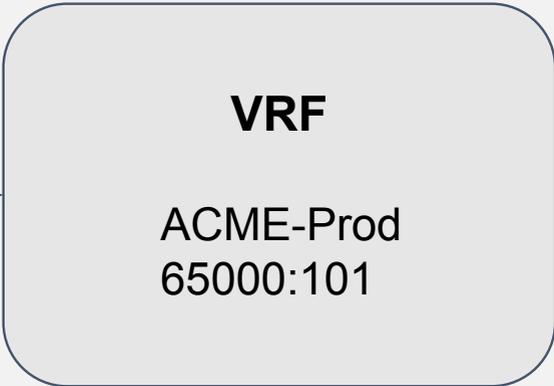

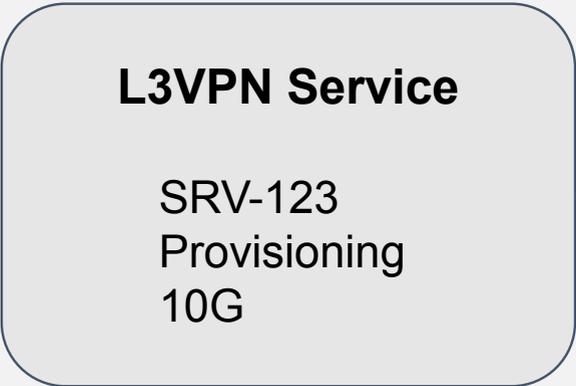

This approach maintains a **clear separation between your service definition and the technical implementation** details

Vendor Abstraction in Practice

Mixed Technology Infrastructure
Same service spanning Cisco on Site A and Arista on Site B

Cross-Platform Services
Cisco routing with Palo Alto firewalls

Vendor complexity is contained in transforms – your service logic remains clean and portable

Deployment Integration

Generated artifacts feed into **your existing tools**. Infrahub works with your current deployment methods, not against them.

Ansible

Push configurations via playbooks

Cisco NSO

Leverage NSO to deploy configurations

Terraform

Infrastructure as code workflows

APIs & Orchestrators

Direct integration with API

Infrahub focuses on generating the right configurations while leveraging your existing deployment pipeline

Conclusion

Everything Starts with Data

- Flexible Source of Truth with branching and version control
- Your services, your way - not forced into rigid templates
- Model exactly what matters to your business

Robust Service Lifecycle Automation

- Beyond scripts and spreadsheets
- Predictable, tested, repeatable processes
- From service request to implementation

Multi-Vendor Environments

- Abstract vendor complexity
- Support complex multi-vendor products
- Simplify migrations and technology changes

The Vendor Migration Scenario

Real case: "We're replacing Cisco with Arista in Region 2"

Traditional Approach

Months of manual configuration rewrites

Risk: Human error in thousands of config changes

With Infracub

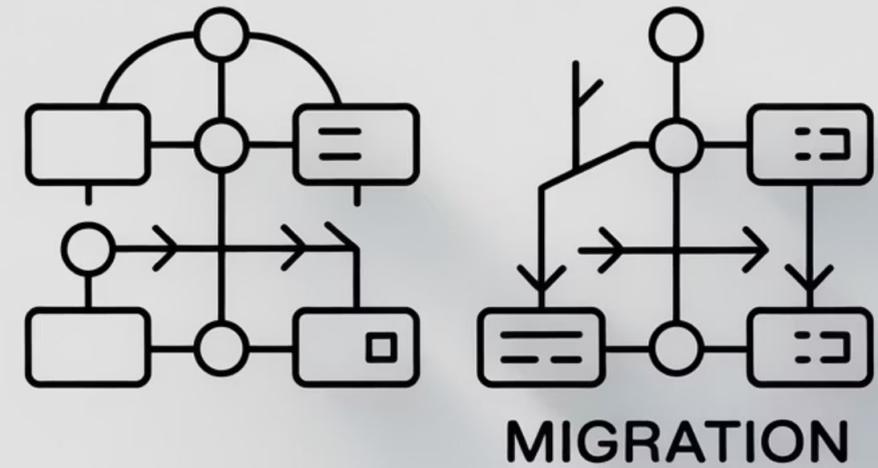

Create a new branch

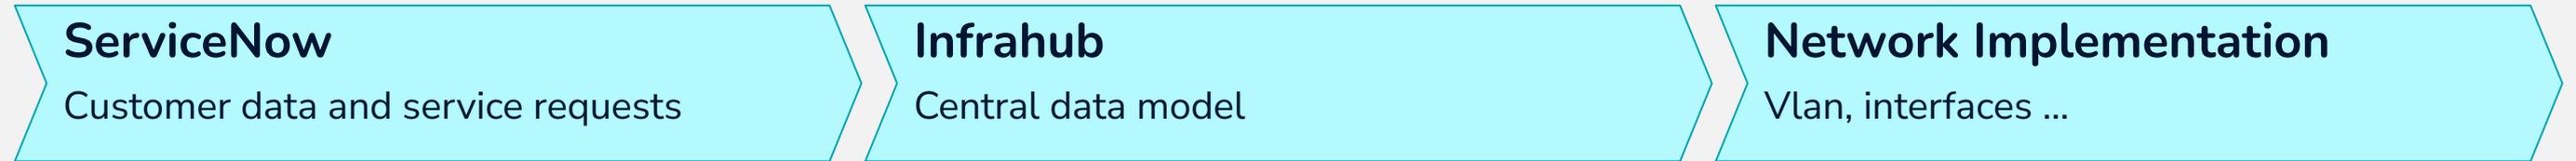

Develop Arista transform

One transform change vs. thousands of manual config rewrites

Same service model, different vendor implementation

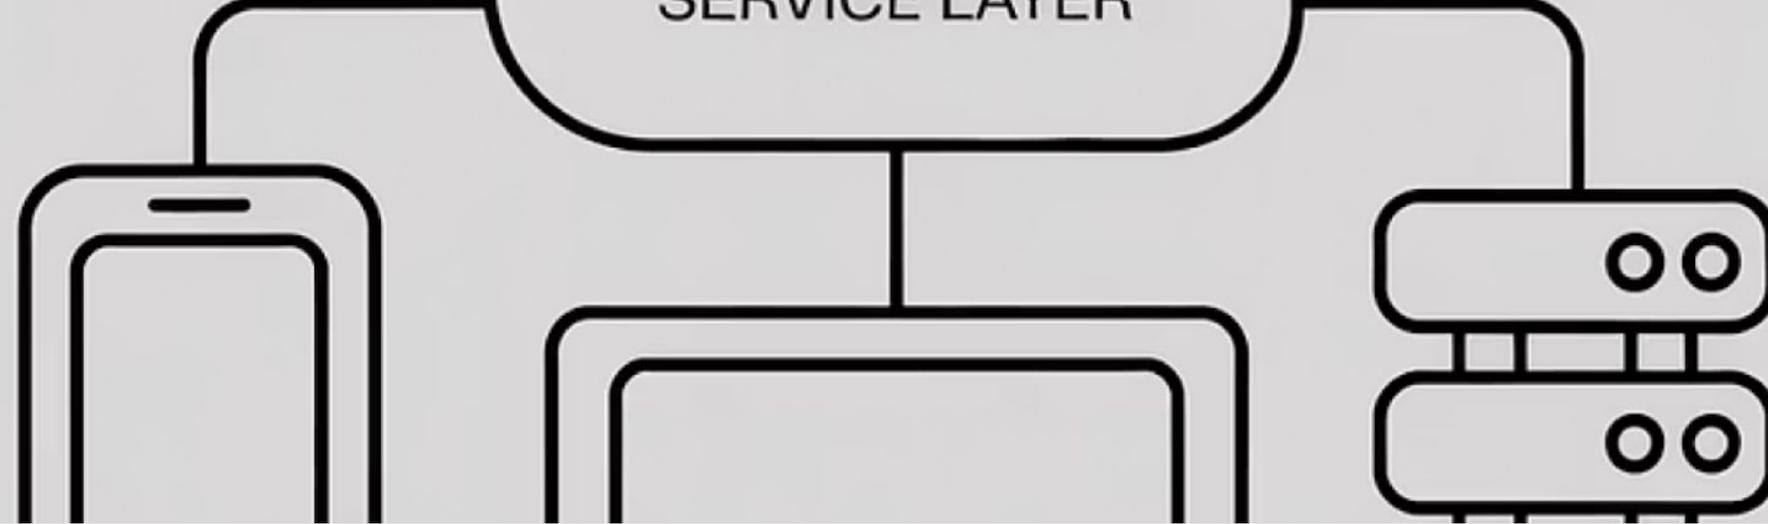

Various data sources

Real-world example: Customer data synced from ServiceNow automatically populates the service model

Key benefit: Create strong integration and a comprehensive overview of your network implementation.

Vendor Abstraction in Practice

Mixed Site Equipment

Same service spanning Cisco on Site A and
Nokia on Site B

Cross-Platform Services

Cisco routing with Palo Alto firewalls

Key insight: Vendor complexity is contained in transforms – your service logic remains clean and portable

From Tribal Knowledge to Code

“Network design lives in Visio diagrams and senior engineers' heads”

Infrahub Generators:

Python scripts that encode your design patterns and automatically translate service requests into implementation

Service Request

"Deploy L3VPN service to these sites"

Generator Logic

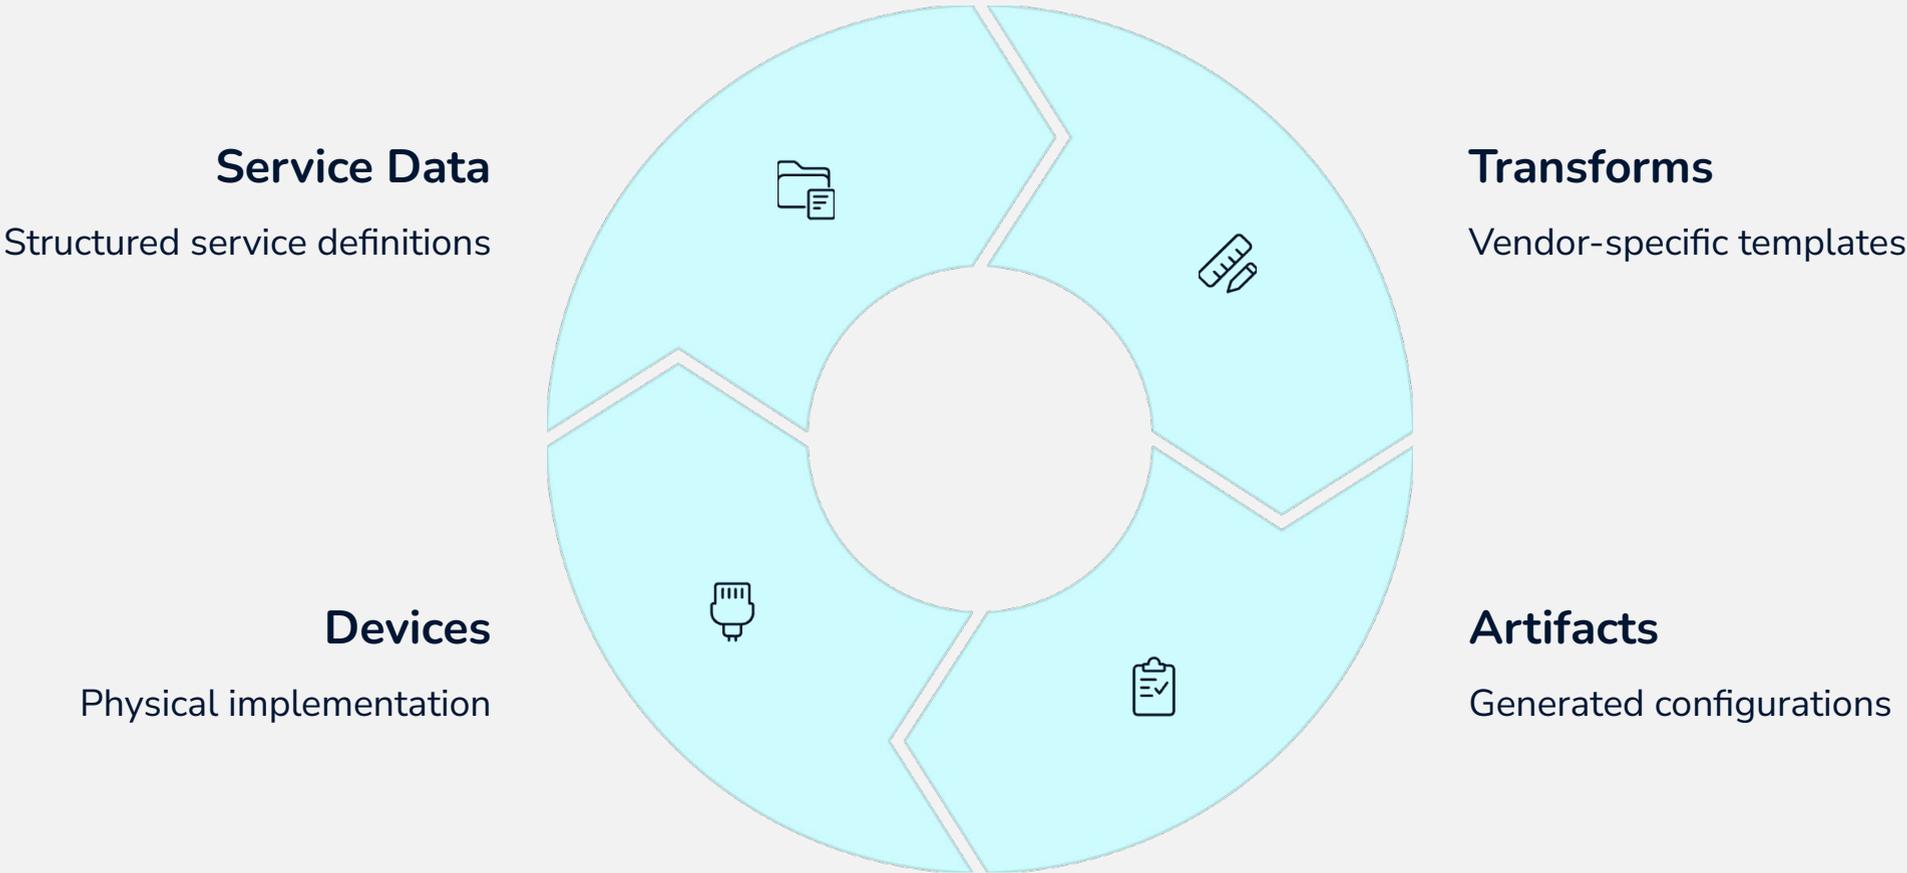

Applies network design rules

Implementation Plan

"Provision VRF, apply QoS profile..."

i Generators also handle service changes like bandwidth upgrades or modifications to service definitions, automatically determining the required implementation changes

From Data Model to Device Reality

Transforms: Templates that turn your data model into vendor-specific configurations

Artifacts: The actual configurations stored and versioned in your system

This approach maintains a clear separation between your business service definition and the technical implementation details
